

# Q5 - Answers

## Attention!

The template for this notebook has been acquired from <https://github.com/ShahabAsoodeh/4ML3>. I've implemented my solutions in the space provided for each algorithm, and wrote the scripts for tasks (1) (2) and (3) at the end of the notebook myself. Make sure to notice the modified code, as my answers for question 5 are within this notebook template provided by Dr. Asoodeh.

## Linear & Polynomial Regression (Analytic)

We will explore **linear regression** and **polynomial regression** using a synthetic dataset ( `synthetic_regression.csv` with columns `x, y` ). All solutions must use **analytic (closed-form)** formulas — **no gradient descent, no library `.fit()`** methods. Implement everything directly in **NumPy**.

## Tasks

### 1. 70/30 Train-Test Split (Unregularized)

- Split the data into 70% train / 30% test (random, reproducible).
- Fit the following models:
  - Linear regression (polynomial degree 1),
  - Polynomial regression with degrees  $k \in \{2, 5, 10, 15\}$ .
- For each model, build the design matrix explicitly: For each datapoint, the row is given by

$$\Phi(x) = [1, x, x^2, \dots, x^k].$$

(let's call the design matrix  $\Phi$  instead of  $X$ .)

- Solve using the equations we derived in class:

$$\theta^* = (\Phi^\top \Phi)^{-1} \Phi^\top \mathbf{y}.$$

- Compute **training error** and **test error**.
- Plot (a) the dataset points with all model fits on one figure, and (b) a **bar chart** of training vs test errors.

## 2. 10-Fold Cross-Validation (Unregularized)

- Implement 10-fold CV yourself (shuffle indices once, split into folds).
- For each degree {1, 2, 5, 10, 15}, compute the **average test error** across folds.
- Plot a **bar chart** comparing the average test error across all models. Conclude the best hypothesis class.

## 3. Repeat (1) and (2) with Ridge Regularization.

- Use ridge regression with:

$$\theta_\lambda^* = (\Phi^\top \Phi + \lambda I)^{-1} \Phi^\top \mathbf{y}.$$

- **Take**  $\lambda = 1$  (fixed).
- Show the same plots: fitted curves, bar chart of train/test errors, and bar chart of 10-fold average test errors.

## Notes

- If any bar chart scale makes some bars invisible, **use a logarithmic y-axis**: `plt.yscale("log")`.
- Keep your code structured and use the provided skeleton below.

## Functions to Implement

For this assignment, you will write the following functions yourself.

Each function connects the mathematical definition we studied in class to working NumPy code.

### 1. `design_matrix_poly_1d(x_column, degree, include_bias=True)`

- Build the design matrix  $\Phi$  for **polynomial regression**:  
[  $\Phi(x) = [1, x, x^2, \dots, x^k]$  ]
  - **Input**: vector of  $x$ -values, degree ( $k$ ).
  - **Output**: design matrix of shape  $(n \times (k + 1))$ .
- 

## 2. normal\_equation(Phi, y)

- Compute the **closed-form OLS solution**:  
[  $\theta^* = (\Phi^\top \Phi)^{-1} \Phi^\top \mathbf{y}$  ] (or use the pseudoinverse if singular).
  - **Input**: design matrix  $\Phi$ , targets  $\mathbf{y}$ .
  - **Output**: regression coefficient vector  $\theta$ .
- 

## 3. ridge\_closed\_form(Phi, y, lam)

- Compute the **ridge regression** solution:  
[  $\theta_\lambda^* = (\Phi^\top \Phi + \lambda I)^{-1} \Phi^\top \mathbf{y}$  ]
  - **Input**: design matrix  $\Phi$ , targets  $\mathbf{y}$ , regularization parameter  $\lambda$ .
  - **Output**: coefficient vector  $\theta$ .
- 

## 4. predict(Phi, theta)

- Generate predictions:  
[  $\hat{\mathbf{y}} = \Phi \theta$  ]
  - **Input**: design matrix  $\Phi$ , coefficients  $\theta$ .
  - **Output**: predicted values.
- 

## 5. err(y\_true, y\_pred)

- Compute the **average squared error**:  
[  $\text{Error} = \frac{1}{n} \sum_i (y_i - \hat{y}_i)^2$  ]
  - **Input:** true values  $\mathbf{y}$ , predicted values  $\hat{\mathbf{y}}$ .
  - **Output:** scalar error.
- 

## Functions to use:

You can use the following functions for reading the data, doing the test-train split and also for the k-fold CV.

### 6. `kfold_indices(n, K, seed=0)`

- Generate index splits for **K-fold cross-validation**.
  - **Input:** dataset size (n), number of folds (K), optional random seed.
  - **Output:** list of `train_idx` and `val_idx` pairs.
- 

### 7. `train_test_split_indices(n, test_ratio=0.3, seed=42)`

- Randomly split dataset into **training** and **test** sets.
  - **Input:** dataset size (n), test ratio, optional random seed.
  - **Output:** two arrays: `train_idx`, `test_idx`.
- 

### 8. `load_csv_xy(path)`

- Load a CSV file with columns `x` and `y`.
  - **Output:**
    - (X): array of shape (n \times 1),
    - (y): vector of shape (n).
-

## Starter Skeleton (fill the TODOs)

Update the CSV path to where you saved `synthetic_regression.csv`.

```
In [26]: import numpy as np
import csv
import matplotlib.pyplot as plt
